SUMMARY

Wnt association with its receptor, Frizzled (Fz), and recruitment by the latter of an adaptor, Dishevelled (Dvl), initiates signaling through at least two distinct pathways (“canonical” and “noncanonical”). Endocytosis and compartmentalization help determine the signaling outcome. Our previous work has shown that Dvl2 links at least one Frizzled family member (Fz4) to clathrin-mediated endocytosis by interacting with the μ 2 subunit of the AP-2 clathrin adaptor, through both a classical endocytic tyrosine motif and a so-called “DEP domain.” We report here the crystal structure of a chimeric protein that mimics the Dvl2- μ 2 complex. The DEP domain binds at one end of the elongated, C-terminal domain of μ 2. This domain:domain interface shows that parts of the μ 2 surface distinct from the tyrosine-motif site can help recruit specific receptors or adaptors into a clathrin coated pit. Mutation of residues at the DEP- μ 2 contact or in the tyrosine motif reduce affinity of Dvl2 for μ 2 and block efficient internalization of Fz4 in response to ligation by Wnt5a. The crystal structure has thus allowed us to identify the specific interaction that leads to Frizzled uptake and to downstream, noncanonical signaling events.

INTRODUCTION

Wnt signaling regulates a number of major developmental events, through at least two classes of pathways (Kikuchi et al., 2009; Logan and Nusse, 2004; Veeman et al., 2003; Wallingford and Habas, 2005; Wehrli and Tomlinson, 1998). Both begin with binding of a Wnt-family ligand to its membrane receptor, Frizzled (Fz), in some cases together with coreceptors such as a low-density lipoprotein receptor-related protein 6 (LRP6) or receptor tyrosine kinases. Frizzled (Fz) can recruit cytosolic adaptors, such as Dishevelled (Dvl), which in turn interact with downstream effectors. Wnt, Frizzled, and Dishev-

elled all represent families of related molecules, leading to a complex diversity of signaling outcomes.

Endocytosis and compartmentalization of Wnt ligands and their receptors and coreceptors help determine the signaling outcome (Chen et al., 2003; Sato et al., 2010; Yu et al., 2007). There is good evidence for selective activation in endosomal compartments of specific branches of Wnt-determined signaling (Blitzer and Nusse, 2006; Dubois et al., 2001; Piddini et al., 2005; Rives et al., 2006; Sato et al., 2010; Seto and Bellen, 2006; Yu et al., 2007). Compartmentalization probably also fine-tunes signaling strength by removing activated receptors from the cell surface and by terminating signaling activity through lysosomal degradation.

Wnt binding to Frizzled, a seven-transmembrane helix protein, and to LRP6, its coreceptor, induces through Dishevelled a signaling cascade known as the “canonical” pathway (He et al., 2004; Tamai et al., 2000; Wehrli et al., 2000). This pathway stabilizes cytosolic β -catenin and leads to gene-specific transcriptional activation. Fz-Dvl complexes also induce a β -catenin independent class of signaling cascades—the “noncanonical” Wnt pathway—by activating the small GTPases RhoA, Rac, and Cdc42 (Boutros and Mlodzik, 1999; Eaton and Simons, 1995; Fanto et al., 2000; Sato et al., 2010). Noncanonical Wnt signaling regulates cytoskeletal reorganization, cell movement, and planar cell polarity (PCP). Its specificity depends on the pairing of particular Wnt ligands with particular Fz family members (e.g., Wnt5A and Fz4). Our previous work (Yu et al., 2007) provides strong evidence that clathrin-mediated endocytosis of Fz4 is necessary to activate noncanonical signaling and that Dvl2 links the relevant Fz receptor to the clathrin endocytic apparatus through an interaction with the endocytic AP-2 clathrin adaptor. A recent study has confirmed this observation by showing that Wnt5a-dependent activation of Rac requires clathrin-mediated internalization of Fz2 (Sato et al., 2010).

AP-2 is a heterotetramer (α , β 2, μ 2, σ 2) that links the clathrin coat to the cargo proteins and membrane lipids of the coated vesicle (Kirchhausen, 1999; Owen et al., 2004). The μ 2 subunit recognizes tyrosine sorting motifs in the cytosolic tails of various membrane proteins and draws these proteins (and their extracellular ligands) into assembling coated pits. We showed in a genome-wide, yeast two-hybrid screen, confirmed by immunoprecipitation and pull-down assays, that Dvl2 and μ 2 interact

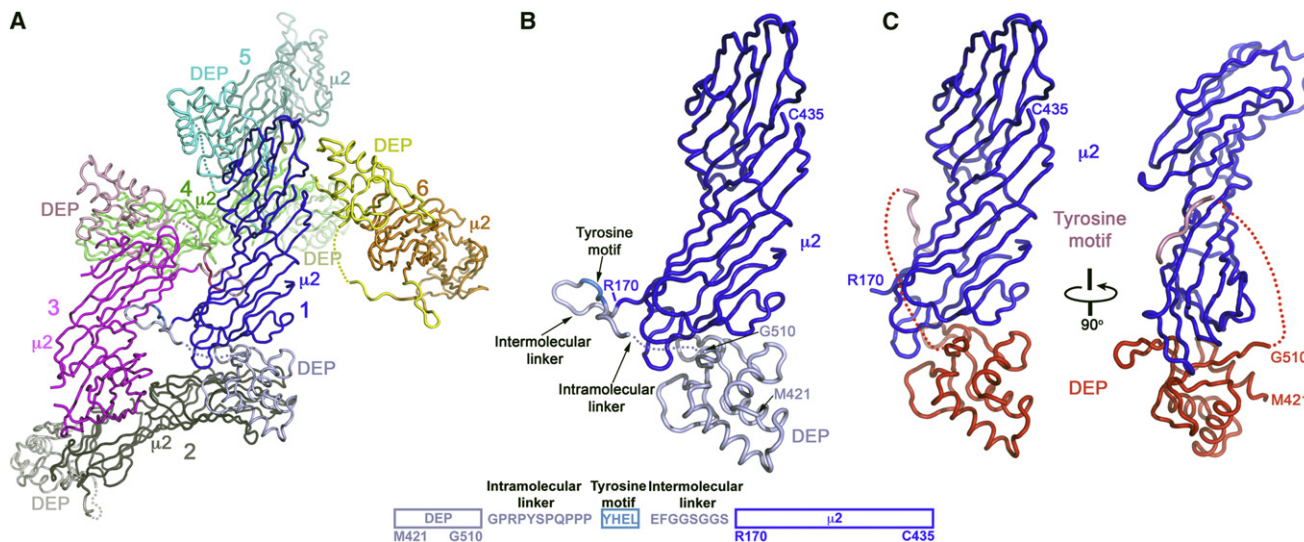

Figure 1. Structure of the Dvl2:μ2 Complex

(A) Crystal packing in one asymmetric unit, showing the “domain swap” of the tyrosine-motif segment. Each polypeptide chain is in a single color range, with the DEP domain much lighter than μ2. In the foreground are two polypeptide chains, in blue (DEP is silver-blue; μ2 is strong blue; tyrosine motif has an intermediate shade) and magenta (DEP is pink; μ2 is strong magenta; tyrosine motif is an intermediate red). These two chains swap tyrosine-motif segments, so that the blue tyrosine motif binds the receiving site on the magenta μ2 and vice versa.

(B) Domain organization of the “blue” chimera.

(C) A composite structure of the DEP domain (red) and the tyrosine motif (pink) of Dvl2 bound to the C-terminal region of μ2 (μ2C) (blue).

and that the interaction is essential for the noncanonical pathway (Yu et al., 2007). Association of Dvl2 and μ2 requires a classical endocytic tyrosine motif in Dvl2 as well as its “DEP domain” (a ~90 residue domain, named after Dishevelled, Egl-10, and Pleckstrin, the proteins in which it was first identified). Single point mutations in the tyrosine motif that affect the Dvl2:μ2 interaction compromise noncanonical Wnt signaling both in isolated cells and in developing *Xenopus* embryos, whereas the Dvl2:μ2 association does not appear to affect canonical Wnt signaling (Yu et al., 2007). Thus, a point mutation that alters endocytic trafficking of the receptor has revealed distinct signaling outcomes for the same molecule at different intracellular locations (plasma membrane versus endosomes). We postulated that trafficking of Wnt/Fz complexes to endosomes is essential for activating noncanonical downstream targets. Because Dvl2 can bind β-arrestin2, it has been proposed that the latter molecule mediates Fz4 internalization indirectly, through its own contacts with AP-2 and clathrin (Chen et al., 2003); our results demonstrating that a direct μ2-Dvl2 contact is required for Fz4 uptake argues against a primary role for β-arrestin2 in directing Fz4 endocytosis.

In the work reported here, we have determined the crystal structure of a chimeric protein that mimics the Dvl2-μ2 complex. It includes the two elements from Dvl2 that we have shown participate in μ2 association: the DEP domain and the tyrosine motif (YHEL). The tyrosine motif binds the C-terminal domain of μ2 (μ2C) at a well-characterized location (Owen and Evans, 1998); the DEP domain binds at one end of the elongated μ2C, docking against a surface that would be exposed even on intact AP-2 (Collins et al., 2002). Mutations, in the tyrosine motif or in its pocket on μ2 or at the DEP-μ2C interface, diminish the affinity of Dvl2 for μ2C. Overexpression of Dvl2 mutants with a compro-

mised DEP:μ2 interaction prevent efficient internalization of Fz4 stimulated by Wnt5a. These results show that the crystal structure has led to identification of the specific interaction that determines Fz4 endocytosis and downstream noncanonical signaling events.

RESULTS

Structure Determination

Truncated forms of murine Dvl2, containing both the DEP domain and the tyrosine motif (YHEL), associate tightly with the C-terminal domain of μ2 (residues 170–435, here designated μ2C) (Yu et al., 2007; see Figure S1A available online). The 60 residue, proline-rich linker segment connecting these two required elements are likely to be unstructured and flexible. We tested a series of deletions and found that a linker of just 11 residues was sufficient for strong binding (Figure S1A). When even this form failed to yield crystals of a complex with μ2C, we constructed a set of single-chain chimeras, with a variable linker between DEP and YHEL and a second variable linker between YHEL and the N terminus of μ2C. Optimization yielded well-ordered crystals of a chimeric protein with linkers of 11 and 8 residues, respectively. This species is a well-behaved monomer in solution (Figures S1B and S1C).

We determined the structure by molecular replacement from diffraction data extending to a minimum Bragg spacing of 3.5 Å (see Experimental Procedures). The space group is C2, with an asymmetric unit that contains six polypeptide chains. The packing is such that the tyrosine motif of one chain interacts with its binding site on μ2C of another chain, related to the former by a noncrystallographic 2-fold, generating a domain-swapped dimer (Figure 1). The only remaining crystallographic contacts

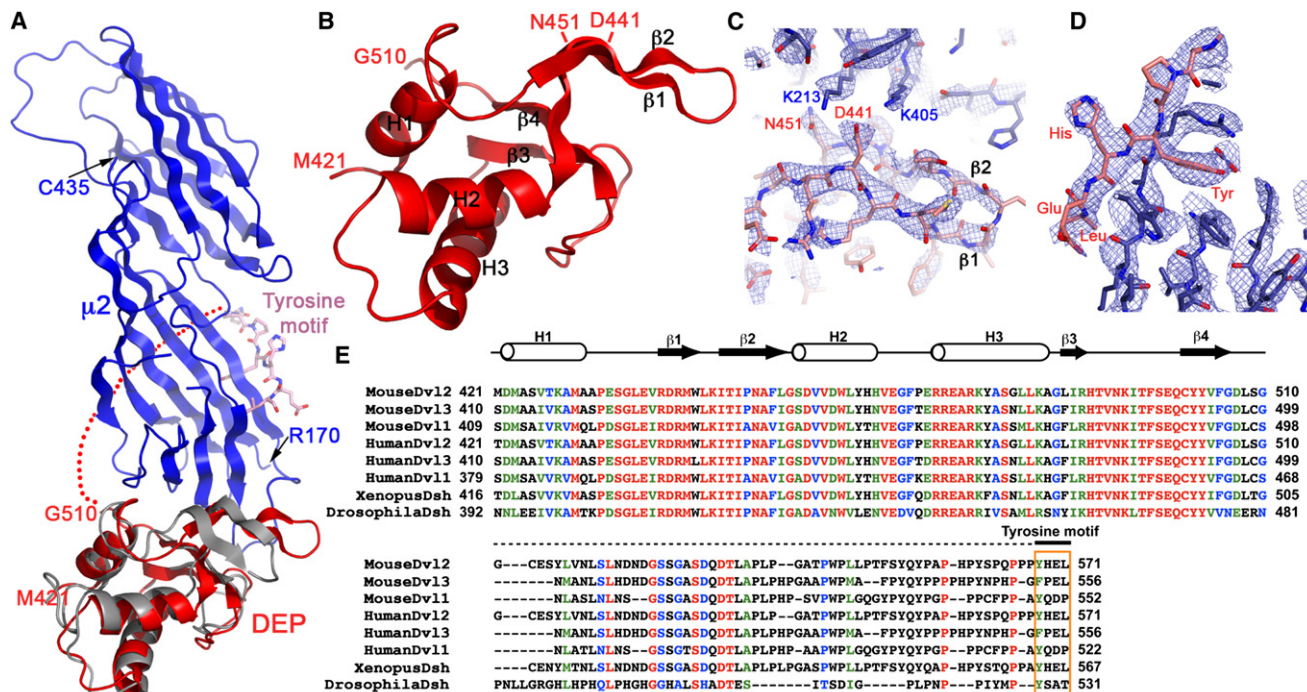

Figure 2. The Dvl2 DEP Domain

Residues from μ2 and DEP domain are colored in blue and red, respectively. (D) The 2Fo-Fc simulated annealed omit map contoured at 2σ showing the YHEL tyrosine motif of Dvl2 and μ2. Residues from μ2 and Dvl2 are colored in blue and red, respectively. (E) Sequence alignment of Dishevelled proteins, generated by ClustalW and manually modified. Residues colored red, green, blue, and black are identical, with strong similarity, weak similarity, and different, respectively.

are between DEP domains and μ2C (Figure 1A). One of these, which we identify experimentally as the functional interaction (see below), is substantially more extensive than the other; the buried surface areas are approximately 1540 Å² and 1000 Å², respectively. The μ2C and Dvl2 elements in our crystals correspond to the protein from rat, but the interface of Dvl2 and μ2C is identical in mouse and man and highly conserved in *Xenopus* (Figure 2).

The Dvl2 DEP Domain

The DEP domain is a 90 residue module with three α helices packed against a small, sharply twisted, 4-stranded β sheet (Figures 1B, 1C, and 2). The loop between strands β1 and β2 is an independent β-ribbon. The solution structure of the murine DEP domain, determined by nuclear magnetic resonance (NMR) spectroscopy (Wong et al., 2000), superposes well on our X-ray structure, except for the β1-β2 loop, which projects at an angle of almost 90° to its direction in the μ2C complex, displacing the tip by about 15 Å. No contacts within the DEP domain need to change in this shift; contacts with μ2C probably determine the new direction of the ribbon.

The DEP:μ2C Interface

The μ2C domain is a gently curved banana-shaped slab, about 80 Å long, 30 Å wide, and less than 20 Å thick. The two crystal-

lographically distinct DEP:μ2C contacts are at opposite ends of this elongated structure. Only the more extensive of the two is close enough to the tyrosine-motif site that an 11 residue linker could connect them. This contact covers nearly the entire surface of one narrow end of the μ2C slab. Principal DEP-domain contributions come from the N-terminal helix (α1), the β1'-β2' ribbon, and strands β3 and β4 of the sheet (Figure 3). A hydrophobic patch, containing DEP-domain residues Ile447, Ile449, Pro450 (all in the β1'-β2' ribbon), and Val504, faces μ2C residues Phe407 and Pro409; Arg489 of the DEP domain, anchored by interaction with carbonyl 505, bridges to Glu211 (buttressed in turn by Arg253) and carbonyl 209 of μ2C; and DEP domain residues Asp441 and Asn451 bridge to μ2C lysines 213 and 405. Glu211, Lys213, Lys405, and Phe407 are conserved in μ1 and μ2, but not in μ3 nor in domains homologous to μC present in the clathrin coat associated proteins, FCHo1/2 and GGAs. Interaction with both μ1 and μ2 is consistent with our previously published data (Yu et al., 2007).

To bind the tyrosine motif, μ2C must shift away from the rest of the AP-2 core, as pointed out in the original analysis of an AP-2 crystal structure (Collins et al., 2002). Early biochemical studies also suggested that AP-2 undergoes a large conformational change to a more open conformation (Rapoport et al., 1997). A recent crystal structure of the AP-2 core bound with a tyrosine peptide motif (PDB ID: 2VGL) (Jackson et al., 2010) shows that

Figure 3. Dvl2:μ2 Interface

(A) Interface of DEP domain and μ2.

(B) Interface of YHEL tyrosine motif and μ2. Salt bridges and H-bonds are shown as yellow dashed lines. Left panels show hydrophilic interactions; right panels, viewed from the opposite side, show hydrophobic interactions. Molecular models colored as in Figure 1C.

not only does μ2C rotate out of its “socket” in the base of the AP-2 core but that the core parts of the α and β subunits also flex, as if to expel μ2C. The μ2C surface contacted by the DEP domain is fully exposed in both the open and closed conformations of AP-2, and we can dock the DEP domain onto both structures without molecular collisions (Figure 4). The μ chain hinge, joining its N- and C-terminal domains, is a 20 residue, flexible segment, disordered in the closed conformation of the AP-2 core structure and partially helical in the open conformation. In both cases it passes near the same μ2C surface but the length and location of its endpoints allow it to avoid the DEP contact completely. By docking of the DEP domain to the exposed tip of μ2C and bringing the tyrosine motif into the vicinity of its binding site, Dvl could also favor opening of AP-2 and capture the open state once formed.

Influence of Mutations at the DEP:μ2C Interface on Association of These Proteins In Vitro

We tested the influence of a set of mutations in μ2C on its association with Dvl2(407–588), a fragment that contains the

DEP domain, the native linker and the YHEL motif. GST-μ2C variants, expressed in *Escherichia coli*, were incubated with His-tagged Dvl2(407–588), and the components retained by a glutathione matrix were analyzed by SDS-PAGE, with Coomassie blue staining to detect GST-containing species and immunoblotting with an anti-His tag antibody to detect Dvl2. Mutation to alanine of each of four interface residues (Glu211, Lys213, Lys405, and Phe407) had only small effects individually but somewhat larger effects in various combinations. Mutations in the tyrosine-motif binding pocket had stronger effects. Thus, the stability of the complex in free solution depends on a combination of the two interactions, with the tyrosine-pocket interaction making the greater contribution. These data are consistent with our observation that the DEP domain alone does not comigrate with μ2C when subjected to size-exclusion chromatography, whereas a fragment (residues 508–588) that lacks DEP but bears the YHEL motif does comigrate (not shown). To demonstrate that the mutated μ2C species are properly folded, we tested the binding of

Figure 4. Superposition of Dvl2:μ2 Complex on the AP-2 Clathrin Adaptor Core

The closed (Collins et al., 2002) and open (Jackson et al., 2010) conformations of the AP-2 core structure are shown as a surface rendering (α chain in green; $\beta 2$ in light blue; $\mu 2$ in blue; $\sigma 2$ in yellow), the Dvl2 DEP domain in worm representation (red), and the YHEL tyrosine motif in side-chain representation (red). The $\mu 2C$ and $\mu 2N$ domains of $\mu 2$ are marked.

a short peptide containing the YQRL motif from TGN38, an integral membrane protein in the trans Golgi network (Figure 5) (Boll et al., 1996; Ohno et al., 1995). Only the form with a compromised tyrosine-motif binding pocket failed to associate with the peptide.

We also tested the influence of a set of mutations in the DEP domain on its association of Dvl2 (417–588) with $\mu 2C$ and with intact AP-2, purified from bovine brain (Figure 6). Because the DEP- $\mu 2$ contact is weak, we chose to use as bait in the pull-down assay the Dvl2 fragment (417–588) containing both the DEP domain and the tyrosine motif. We therefore were testing for modulations in apparent affinity, rather than all-or-none effects. Mutating the tyrosine residue of YHEL results in a substantial loss of binding as expected (Yu et al., 2007). Single polar amino acid changes (Asp441Lys, Asn451Ala, Arg489Ala) reduced affinity; double or triple mutation did not produce a further decrease (Figure 6). We conclude that even the single substitutions in the DEP domain fully destabilize the DEP: $\mu 2$ interface, and further changes do not affect the basal affinity determined by the tyrosine motif.

The K to M mutation in the DEP domain corresponding to the *dsh¹* allele in fruit flies first defined the PCP pathway (Axelrod et al., 1998). Two additional mutations, Lys446Ala and Lys446-Met, at a position near the DEP: $\mu 2$ interface, but not part of a direct contact, also influence $\mu 2$ affinity (roughly a 2-fold decrease, data not shown). Position 446 is at the tip of the $\beta 1$ - $\beta 2$ ribbon, which appears to have alternative possible conformations (see comparison of the conformation of this loop in the complex with $\mu 2C$ and in the solution structure of the DEP domain alone). Substitutions at the tip of the ribbon could influence its conformational preferences and thus affect the association of the domain with $\mu 2C$. For example, a very small change in the conformation of the $\beta 1$ - $\beta 2$ turn would allow Lys446 to form a salt bridge with Asp417 on $\mu 2$.

Effect of Mutations on Endocytosis of Frizzled

We took advantage of the mutational analysis just described to test whether the observed interface between $\mu 2$ and DEP is indeed critical for Frizzled internalization. For this purpose, we followed a method that we had developed previously to identify

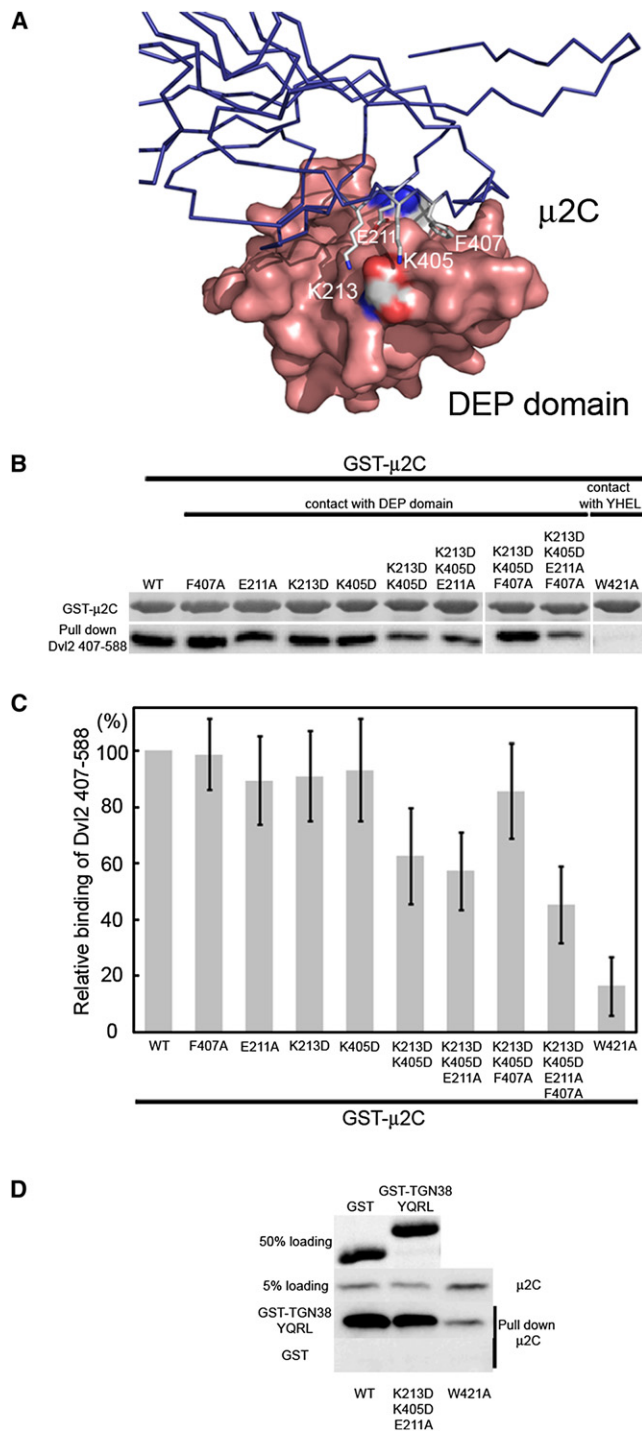

Figure 5. Influence of Specific Mutations in $\mu 2$ on Its Association with the DEP Domain of Dvl2

(A) Schematic representation of the Dvl2: $\mu 2$ interface; $\mu 2$ C (blue) is represented as a ribbon diagram; DEP domain (pink), as a surface rendering. Residues E211, K213, K405, and F407 of $\mu 2$ C, that make close contacts with the DEP domain of Dishevelled 2 are highlighted.

(B) Pull-down assay with bacterially expressed wild-type or point mutant $\mu 2$ C fused to GST and His-tagged Dvl2 407–588. Bound GST-containing proteins were detected by SDS-PAGE followed by Coomassie blue staining (50% input). Bound Dvl2 407–588 proteins were detected from a second sample

proteins participating in endocytosis of Fz4 (Yu et al., 2007). We expressed HA-tagged Fz4 and Myc-tagged Dvl2 in HEK293T cells and monitored internalization and degradation of the HA-Fz4 by following uptake of an anti-HA antibody added to the medium immediately before adding Wnt and PMA.

As shown in Figure 7, treatment with Wnt5A and PMA for 20 min stimulates uptake of Fz4, as indicated by the punctate distribution of anti-HA within cells coexpressing wild-type Dvl2. Note that in cells with complete Frizzled endocytosis, Dvl2 separates from Fz4 following uptake (Figures 7A and 7B) (Dvl2 YHEL). As reported in our earlier paper (Yu et al., 2007), a point mutation in the YHEL motif of Dvl2 blocked internalization of HA-Fz4 (Figures 7A and 7B) (Dvl2 AHEA), as did expression of Dvl2 K446M (Figures 7A and 7B) (Dvl2 K446M); the latter mutant is the equivalent of K417M in *Drosophila* Dsh, the original *dsh*¹ allele identified with a defect in noncanonical Wnt signaling (Axelrod et al., 1998; Boutros et al., 2000; Perrimon and Mahowald, 1987). Expression of Dvl2 D441K,N451A,R489A—a triple mutant combining the three interface mutations characterized in the experiments shown in Figure 6—allowed a limited level of internalization following treatment with Wnt5A and PMA (Figures 7A and 7B) (Dvl2 D441K,N451A,R489A), but substantially less than expression of wild-type Dvl2. The relative strengths of the AHEA and D441K,N451A,R489A mutant phenotypes correspond to their relative effects on $\mu 2$ binding. The tyrosine-motif mutation, which eliminates detectable association of Dvl2 and $\mu 2$ C in vitro, completely disables endocytosis of Fz4; the triple mutation at the DEP-domain: $\mu 2$ C interface has a partial effect.

Like wild-type Dvl2, the Dvl2 AHEA and D441K,N451A,R489A mutants relocate to the cell periphery when Fz4 is overexpressed, even without addition of Wnt5A/PMA. Dvl2 K446M does not. This observation agrees with previous reports that the K446M mutation in the DEP domain prevents membrane recruitment of Dvl2 and suggests that modifications at the tip of the $\beta 1'$ - $\beta 2'$ ribbon affect an earlier step in Frizzled endocytosis than the one affected by alterations in the surface containing Asp441, Asn451, and Arg489.

DISCUSSION

The structure of the Dvl2: $\mu 2$ C complex just described shows specific features of the bipartite interaction inferred from our earlier work. One component of the contact is the familiar tyrosine-motif interaction, essentially the same as those analyzed previously (Boll et al., 1996; Modis et al., 2001; Ohno et al., 1995; Owen and Evans, 1998). Like all the cargo-adaptor

processed identically, by western blot analysis with the antibody specific for the His tag in Dvl2 407–588 (50% input). The results are representative of four independent experiments.

(C) Relative binding of Dvl2 407–588 to the GST- $\mu 2$ C wild-type and mutants used in (B). The binding of the wild-type $\mu 2$ C was set as 100%. Data correspond to average \pm SD from four experiments.

(D) Pull-down assay with a short peptide containing the YQRL sorting motif from TGN38 fused to GST and His-tagged Dvl2 407–588. Bound GST-containing proteins were detected by SDS-PAGE followed by Coomassie blue staining (50% input). Bound $\mu 2$ C was detected from a second sample processed identically, by western blot analysis with the antibody specific for the His tag in $\mu 2$ C (50% input). The results are representative of three independent experiments.

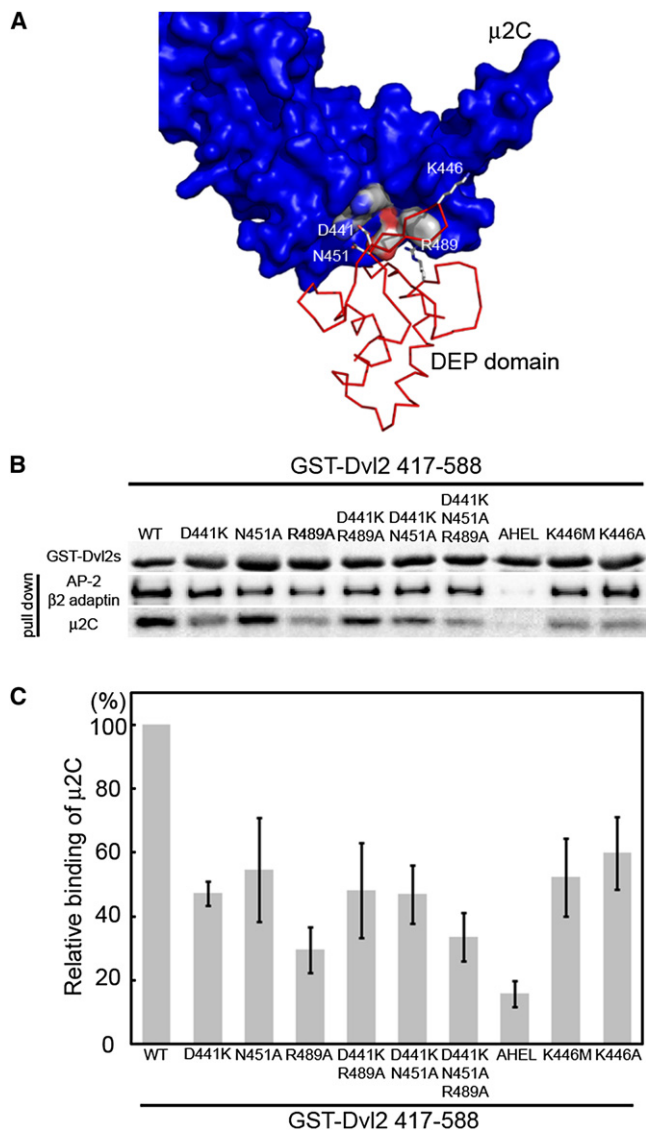

Figure 6. Influence of Specific Mutations in the DEP Domain of Dvl2 on Its Association with μ 2C or with the AP-2 Clathrin Adaptor

(A) Schematic representation of the Dvl2: μ 2C interface; μ 2C (blue) is represented as a surface rendering and the DEP domain (pink) is shown as a ribbon diagram. Residues D441, R489, and N451 of the DEP domain at the interface with μ 2C are highlighted. K446 is also shown.

(B) Pull-down assay with GST-Dvl2 417-588 and AP-2 clathrin adaptor purified from calf brain coated vesicles or recombinant μ 2C. Bound GST-containing proteins were detected by SDS-PAGE followed by Coomassie blue staining (50% input). Bound AP-2 or μ 2C were detected from a second sample processed identically, by western blot analysis with the antibody specific for β 1,2-adaptins of AP-2 or with the antibody specific for the His tag for μ 2C (50% input). The results are representative of three experiments.

(C) Relative binding of μ 2C to the GST-Dvl2 407-588 variants used in (B). The binding of the wild-type μ 2C was set as 100%. Data correspond to average \pm SD from three independent experiments.

interactions in structures so far determined, this contact is a “peptide-domain” association, with a short motif on an unfolded segment of the cargo polypeptide chain inserted into a surface binding site on a well-folded domain of the adaptor

subunit (Figure 4). The other component of the Dvl2: μ 2C contact is a new “domain-domain” interface, with complementary surfaces of two folded structures docked against each other.

The interaction between the DEP domain and μ 2C helps resolve a puzzle posed by the contrast between the very extensive surface presented by μ 2C and the extremely restricted patch dedicated to recognition of the tyrosine motif. The DEP interface now shows that a part of the exposed μ 2C surface distinct from the tyrosine-motif site participates in cargo binding. The result suggests that other parts of that surface may also have partners, as yet unidentified. The incorporation of two interaction modes into one cargo molecule further suggests that combinatorial recognition (and combinatorial cargo addressing) may likewise be more widespread than hitherto suspected.

Frizzled recruits Dishevelled to the plasma membrane, in part through an interaction between a KTxxxW motif at the Frizzled C terminus and a Dishevelled PDZ domain (Punchihewa et al., 2009; Zhang et al., 2009). The recruitment, which is Wnt independent, also requires the DEP domain. The product of the *dsh*¹(K446M) allele has a defect in this translocation (Axelrod et al., 1998). Some recently published work suggests that a positively charged patch containing lysines 477 and 484 in the DEP domain contributes to membrane recruitment of Dishevelled, perhaps through interaction with negatively charged lipid head groups (Simons et al., 2009). These residues are not in the contact with μ 2C in the crystal structure, and we have shown that mutation to glutamic acid of Lys477 and Lys484 in the DEP domain of Dvl2 does not affect the Dvl2: μ 2C interaction (data not shown). The superposition in Figure 4 shows that when Dvl2 binds AP-2, the surface of the DEP domain that bears these lysine residues faces in the same direction as does the site on the α chain of the AP-2 core that binds phosphatidylinositol-4,5-bisphosphate (Collins et al., 2002). The two interactions could occur together on a roughly planar lipid bilayer if the μ 2C domain were to rock slightly out of its position in the unliganded AP-2 complex (as it must do, to open up the tyrosine-motif site). Lys446 does not lie in the same plane, however, and if the DEP domain were oriented to present lysines 477 and 484 to lipid head groups, Lys446 would be displaced by about 35 Å from the lipid bilayer surface. The loss of membrane recruitment when this residue is changed to Met would therefore need to come from disruption of some other contact. A cytoplasmic segment of Fz4 is the most likely candidate for this additional contact, because the Lys446Met mutation eliminates even the Wnt-independent (and hence AP-2 independent) membrane recruitment of Dvl2 by Fz4.

Uptake of the Frizzled:Dishevelled complex appears to require conformational changes in Frizzled. Transient expression of the two proteins leads to membrane recruitment of Dishevelled, but endocytosis requires Wnt. One possibility is that unliganded Frizzled interferes with the DEP-domain: μ 2C contact seen in our structure and that activation by Wnt relieves this inhibition (Punchihewa et al., 2009). There is evidence for direct DEP domain:seven transmembrane-protein contact in other contexts (Ballon et al., 2006). Frizzled might also contact μ 2 directly, as Dvl2 Lys446 (the site of the potential Frizzled contact just proposed) is adjacent to the μ 2 interface.

If internalization of Frizzled is an immediate result of Wnt binding, signaling from the noncanonical branch of the Wnt

Figure 7. Effect of Mutations in Dvl2 that Interfere with AP-2 Binding on Internalization of Activated Fz4

(A) HEK293T cells were cotransfected with plasmids encoding HA-Fz4 (green) together with Myc-tagged wild-type mouse Dvl2 bearing the YHEL sorting motif (Dvl2 YHEL, red), Myc-tagged Dishevelled2 with AHEA instead of the YHEL motif (Dvl2 AHEA, red), Myc-tagged Dishevelled2 with the K446M mutation in the DEP domain (Dvl2 K446M, red), or Myc-tagged Dishevelled2 with the triple mutation D441K, N451A, and R489A in the DEP domain (Dvl2 D441K/N451A/R489A, red). After 24 hr, cells were incubated at 37°C for 10 min with an antibody specific for the HA-epitope (green), then for 20 min, also at 37°C, with fresh medium containing Wnt5A/PMA. Cells were fixed, permeabilized, and processed for immunofluorescence. Representative examples from 15 independent fields from two independent experiments for each condition are shown using equal imaging settings.

(B) Analysis of images from fields corresponding to the experiments depicted in A. The extent of Fz4 internalization was scored in cells coexpressing Dvl2 and Fz4 according to previously established criteria (Yu et al., 2007): (1) HA-Fz4 signal at the cell surface (none), (2) a mixture of HA-Fz4 signals at the cell surface together with a punctate intracellular pattern (partial) and (3) no discernible HA-Fz4 signal at the cell surface together with a weak intracellular punctate pattern (complete). About 300 cells were analyzed for each of the experimental conditions.

pathway may occur in early endosomes, after uptake of the activated receptor, rather than only at the cell surface. Recent work suggests that Rac1, a downstream component of the non-canonical Wnt signaling pathway, is activated on the surface of early endosomes by recruitment of the Rac1-specific GEF, Tiam1 (Palamidessi et al., 2008). Moreover, this endosomal activation is linked to actin dynamics and cell migration. The interaction documented here couples the Wnt-activated Dishevelled-Frizzled complex to the machinery likely to bring it into the appropriate endosomal compartment, with Tiam1 as one of its downstream effectors.

EXPERIMENTAL PROCEDURES

Reagents, Clones, and Constructs

Cell lines, reagents, and antibodies have been described previously (Yu et al., 2007). Plasmids encoding HA-Fz4, Myc-Dvl2, GST-TGN38-YQRL have also been described (Boll et al., 2002; Ohno et al., 1995; Yu et al., 2007). Plasmids

encoding the GST-tagged Dvl2 417-588 and μ 2 170-435 (μ 2C) were generated using the pGEX-4T1 bacterial expression vector. Plasmids expressing His-tagged Dvl2 407-588 and μ 2C were generated using the pPROEX-HTC bacterial expression vector. Multiple point mutations in the specific constructs were introduced using the QuickChange protocol (Stratagene). To construct the plasmid expressing the chimeric protein, cDNA encoding the fragment of Dvl2 from residue 407 to 571 was cloned into pPROEX-HTC plasmid following the His tag and the TEV protease cleavage site. Two Sac II cleavage sites were inserted after residues 511 and 559 using the QuickChange protocol. The region between the added Sac II sites was removed by Sac II digestion and religation. The C-terminal domain of μ 2 adaptin (μ 2C) was amplified with a forward primer with an overhanging region encoding EcoRI site followed by a Gly-Gly-Ser-Gly-Gly-Ser linker and a reverse primer encoding an XhoI site and the C-terminal end of μ 2 adaptin. The PCR fragment was digested and inserted into the proEXHTC-Dvl2 407-571 plasmid with the internal deletion. The resulting construct expresses a protein containing the DEP domain of Dvl2 (407-510), a shortened 11 residue intramolecular loop, the YHEL motif, a GGSGGS linker, and the C-terminal domain of μ 2 adaptin (μ 2C).

Expression, Purification, and Crystallization of the Dvl2: μ 2C Chimera

The recombinant His-tagged protein with a TEV cleavage site following the tag was expressed in *E. coli* at 16°C. The protein was purified by passage over a Ni-NTA resin (GE Healthcare Life Sciences) and then subjected to TEV cleavage. The detached protein was further purified by chromatography on SP-Sepharose HP followed by gel filtration on S200 (GE Healthcare Life Sciences). The final concentration was 20 mg/ml in 20 mM HEPES (pH 7.5),

Table 1. Data Collection and Refinement Statistics

Data Collection	
Space group	C2
Cell dimensions	
a, b, c (Å)	292.4, 98.1, 171.3
β (°)	122.0
Resolution (Å)	100–3.5
R _{sym} (%) ^{a,b}	11.2 (77.4)
I/σ (I) ²	11.3 (1.5)
Completeness (%) ²	99.3 (97.0)
Redundancy ^b	3.6 (3.5)
Refinement	
Resolution (Å)	3.5
No. reflections	51395
R _{work} /R _{free} (%) ^c	30.8/33.5
Rmsd	
Bond length (Å)	0.011
Bond angle (°)	1.4
Ramachandran analysis	
Favored/outlier (%)	87.6/0.0
Total residues	2006

^a $R_{sym} = \sum_j \sum_i |I_j - \langle I_j \rangle| / \sum_j I_j$, where I_j is the intensity measurement for reflection j and $\langle I_j \rangle$ is the mean intensity for multiply recorded reflections.

^b Values in parentheses are for the outermost resolution shell.

^c $R_{work, free} = \sum ||F_{obs}| - |F_{calc}|| / \sum |F_{obs}|$, where the working and free R factors are calculated using the working and free reflection sets, respectively.

0.5 M NaCl, and 2 mM dithiothreitol (DTT). Single crystals (typical size 0.3 × 0.2 × 0.2 mm) were obtained with hanging-drop vapor diffusion at 20°C by mixing 1 μl of the protein solution and 1 μl of the reservoir solution (0.7 M K/Na tartrate, 0.1 M sodium citrate (pH 5.5), 10 mM DTT). Cryoprotection for X-ray data collection in a boiling nitrogen stream was in 25% glycerol.

Data Collection and Structure Determination

Diffraction data were collected at the Advanced Photon Source, beamline 24-ID-E, and processed and scaled with HKL2000 (Otwinowski and Minor, 1997). Data to a minimum Bragg spacing of 3.5 Å were used for structure determination and refinement (Table 1). The structure was determined by molecular replacement using the program Phaser. The C-terminal domain of a murine μ2 adaptin subunit without a bound endocytic tyrosine-motif containing peptide (PDB entry 1BW8) and a DEP domain (PDB entry 1FSH) were used as search models. Maps were inspected and models modified with the program Coot. The model coordinates were refined with CNS (Brunger et al., 1998). A test set containing 5% of all reflections was used throughout the refinement. The intermolecular linker was built, and the DEP domain rebuilt, after the first round of rigid body refinement, positional refinement, and density modification with 6-fold noncrystallographic symmetry averaging. Linker connectivity's were unambiguous. Well-ordered density was present in the initial, molecular-replacement density map for the linker that bridges μ2C R170 and the tyrosine motif bound to μ2C of an adjacent molecule. Scattered density appeared after a few cycles of refinement between the tyrosine motif and the C terminus of the DEP domain associated with the μ2C covalently linked to that tyrosine motif. The model was further refined and rebuilt until the R factors ceased to drop. The stereochemistry of the models was monitored using Molprobity (Davis et al., 2007). Structural superposition was performed using LSQMAN from Uppsala Software Factory. Pymol was used to generate figures in this paper.

In Vitro GST Pull-Down

Purified GST-tagged proteins (~2 μg) were adsorbed to 7.5 μl glutathione beads in 20 mM HEPES (pH 7.5), 250 mM NaCl, 1 mM EDTA, 1 mM DTT.

Purified proteins (AP-2, His-tagged Dvl2 407–588 and His-tagged μ2C) at final concentrations of 2.5, 15, and 1 μg/ml were incubated with immobilized GST-tagged proteins for 1 hr at 4°C in 200 μl buffer containing 0.2 mg/ml BSA, 100 mM MES (pH 7.0), 150 mM KCl, 1 mM EDTA, 1 mM DTT, and 1% Triton X-100. The beads were washed three times with the same buffer. Bound proteins were analyzed by SDS-PAGE and western blotting. The data represent the results obtained from three or four independent experiments.

Internalization Assay

Internalization of HA-Fz4 in HEK293T cells expressing different Myc-Dvl2 proteins was stimulated with Wnt5A-conditioned medium in the presence of 1 μM PMA for 20 min as described previously (Yu et al., 2007). Images were acquired using a Marianas system (Intelligent Imaging Innovations, Denver, CO) equipped with inverted microscope (Zeiss, Axio-Observer using a Plan-Apo 63× 1.4 NA objective), a Yokogawa spinning disk confocal unit (model CSU-22), a computer-controlled spherical aberration correction unit (Intelligent Imaging Innovations) and a Photometrics Cascade EM CCD camera. All the hardware was controlled by SlideBook version 4.2 (Intelligent Imaging Innovations). Single focal planes are shown approximately centered in the middle of the cell. Representative images correspond to data obtained from two independent experiments and more than 300 cells.

ACCESSION NUMBERS

Coordinates have been deposited in the Protein Data Bank (PDB ID: 3ML6).

SUPPLEMENTAL INFORMATION

Supplemental Information includes one figure and can be found with this article online at doi:10.1016/j.str.2010.07.010.

ACKNOWLEDGMENTS

We thank the staff of the Northeast Collaborative Access Team at the Advanced Photon Source for assistance with X-ray diffraction data collection, Kevin Corbett for collecting diffraction data, Iris Rapoport, Werner Boll, and Till Böcking for AP-2 preparations and Eric Marino for maintaining the fluorescence microscopy resource. The research was supported by NIH grant GM36548, 075252, and U54 AI057159 (NERCE Imaging Resource) (to T.K.). Y.X. acknowledges a Ruth Kirschstein National Research Service Award. S.C.H. is an Investigator in the Howard Hughes Medical Institute.
